The Common-Drain Amplifier

Basic Circuit

Fig. 1 shows the circuit diagram of a single stage common-drain amplifier. The object is to solve for the small-signal voltage gain, input resistance, and output resistance.

DC Solution

(a) Replace the capacitors with open circuits. Look out of the 3 MOSFET terminals and make Thévenin equivalent circuits as shown in Fig. 2.

\[ V_{GG} = \frac{V^+ R_2 + V^- R_1}{R_1 + R_2} \quad R_{GG} = R_1 \parallel R_2 \]

\[ V_{SS} = V^- \quad R_{SS} = R_S \quad V_{DD} = V^+ \quad R_{DD} = 0 \]

(b) Write the loop equation between the \( V_{GG} \) and the \( V_{SS} \) nodes.

\[ V_{GG} - V_{SS} = V_{GS} + I_S R_{SS} = V_{GS} + I_D R_{SS} \]

(c) Use the equation for the drain current to solve for \( V_{GS} \).

\[ V_{GS} = \sqrt{\frac{I_D}{K}} + V_{TO} \]
(d) Solve the equations simultaneously.

\[ I_D R_{SS} + \sqrt{\frac{I_D}{K}} + [(V_{GG} - V_{SS}) - V_{TO}] = 0 \]

(e) Let \( V_1 = (V_{GG} - V_{SS}) - V_{TO} \). Solve the quadratic for \( I_D \).

\[ I_D = \left( \frac{\sqrt{1 + 4K V_1 R_{SS}} - 1}{2R_{SS}\sqrt{K}} \right)^2 \]

(d) Verify that \( V_{DS} > V_{GS} - V_{TO} = \sqrt{I_D/K} \) for the active mode.

\[ V_{DS} = V_D - V_S = (V_{DD} - I_D R_{DD}) - V_{GG} = V_{DD} - V_{SS} - I_D R_{DD} \]

**Small-Signal or AC Solutions**

(a) Redraw the circuit with \( V^+ = V^- = 0 \) and all capacitors replaced with short circuits as shown in Fig. ??.

(b) Calculate \( g_m, r_s, \) and \( r_0 \) from the DC solution.

\[ g_m = 2\sqrt{K I_D} \quad r_s = \frac{1}{g_m} \quad r_0 = \frac{V_A + V_{CE}}{I_C} \]

(c) Replace the circuits looking out of the gate with a Thévenin equivalent circuit as shown in Fig. 4.

\[ v_{tg} = v_i \frac{R_1 \| R_2}{R_s + R_1 \| R_2} \quad R_{tg} = R_1 \| R_2 \]
Figure 3: Signal circuit.

Figure 4: Signal circuit with Thévenin gate circuit.
Exact Solution

Note that the Thévenin resistance $R_{td}$ seen looking out of the drain is zero. This exact solution is also valid for circuits where $R_{td} \neq 0$.

(a) Replace the circuit seen looking into the source with its Thévenin equivalent circuit as shown in Fig. 5. Solve for $v_{s(oc)}$.

$$v_{s(oc)} = v_{tg} \frac{r_0}{r_s + r_0} \quad r_{is} = r_s \frac{r_0 + R_{td}}{r_s + r_0} \quad R_{td} = 0$$

Figure 5: Thévenin source circuit.

(b) Solve for $v_o$.

$$v_o = v_{s(oc)} \frac{R_S \| R_L}{r_{is} + R_S \| R_L} = v_i \frac{R_1 \| R_2}{R_s + R_1 \| R_2 r_{is} + R_S \| R_L}$$

(c) Solve for the voltage gain.

$$A_v = \frac{v_o}{v_i} = \frac{R_1 \| R_2}{R_s + R_1 \| R_2 r_{is} + R_S \| R_L}$$

(d) Solve for $r_{in}$.

$$r_{in} = R_1 \| R_2$$

(e) Solve for $r_{out}$.

$$r_{out} = r_{is} \| R_S$$

(f) Special case for $r_0 = \infty$.

$$v_{s(oc)} = v_{tg} \quad r_{is} = r_s$$

Example 1 For the CS amplifier of Fig. ??, it is given that $R_i = 5 \, \text{k}\Omega$, $R_1 = 5 \, \text{M}\Omega$, $R_2 = 1 \, \text{M}\Omega$, $R_D = 10 \, \text{k}\Omega$, $R_S = 3 \, \text{k}\Omega$, $R_3 = 50 \, \Omega$, $R_L = 20 \, \text{k}\Omega$, $V^+ = 24 \, \text{V}$, $V^- = -24 \, \text{V}$, $K_0 = 0.001 \, \text{A} / \text{V}^2$, $V_{TO} = 1.75 \, \text{V}$, $\lambda = 0.016 \, \text{V}^{-1}$. Solve for the gain $A_v = v_o / v_i$, the input resistance $r_{in}$, and the output resistance $r_{out}$. The capacitors can be assumed to be ac short circuits at the operating frequency.
Solution. For the dc bias solution, replace all capacitors with open circuits. The Thévenin voltage and resistance seen looking out of the gate are

\[ V_{GG} = \frac{V^+ R_2 + V^- R_1}{R_1 + R_2} = -16 \text{ V} \quad R_{BB} = R_1 || R_2 = 833.3 \text{ k}\Omega \]

The Thévenin voltage and resistance seen looking out of the source are \( V_{SS} = V^- \) and \( R_{SS} = R_S \). To calculate \( I_D \), we neglect the Early effect by setting \( K = K_0 \). The bias equation for \( I_D \) is

\[ I_D = \left( \frac{\sqrt{1 + 4KV^+ R_{SS}} - 1}{2\sqrt{KR_{SS}}} \right)^2 = 1.655 \text{ mA} \]

To test for the active mode, we calculate the drain-source voltage

\[ V_{DS} = V_D - V_S = V^+ - (V^- + I_D R_{SS}) = 43.036 \text{ V} \]

This must be greater than \( V_{GS} - V_{TO} = \sqrt{I_D/K} = 1.286 \text{ V} \). It follows that the MOSFET is biased in its active mode.

For the small-signal ac analysis, we need \( g_m, r_s, \) and \( r_0 \). When the Early effect is accounted for, the new value of \( K \) is given by

\[ K = K_0 (1 + \lambda V_{DS}) = 1.689 \times 10^{-3} \text{ A/V}^2 \]

Note that this is an approximation because the Early effect was neglected in calculating \( V_{DS} \). However, the approximation should be close to the true value. It follows that \( g_m, r_s, \) and \( r_0 \) are given by

\[ g_m = 2\sqrt{KI_D} = 3.343 \times 10^{-3} \text{ A/V} \quad r_s = \frac{1}{g_m} = 299.135 \text{ } \Omega \]

\[ r_0 = \frac{\lambda^{-1} + V_{DS}}{I_D} = 63.78 \text{ k}\Omega \]

For the small-signal analysis, \( V^+ \) and \( V^- \) are zeroed and the three capacitors are replaced with ac short circuits. The Thévenin voltage and resistance seen looking out of the gate are given by

\[ v_{tg} = v_i \frac{R_1 || R_2}{R_i + R_1 || R_2} = 0.994v_i \quad R_{tg} = R_1 || R_1 || R_2 = 4.97 \text{ k}\Omega \]

The Thévenin voltage and resistance seen looking into the source are

\[ v_{s(oc)} = v_{tg} \frac{r_0}{r_s + r_0} = 0.989v_i \quad R_{td} = 0 \quad r_{is} = r_s \frac{r_0 + R_{td}}{r_s + r_0} = 297.738 \text{ } \Omega \]

The output voltage is given by

\[ v_o = v_{s(oc)} \frac{R_S || R_L}{r_{is} + R_S || R_L} = 0.888v_i \]

Thus the voltage gain is

\[ A_v = \frac{v_o}{v_i} = 0.888 \]

The input and output resistances are given by

\[ r_{in} = R_1 || R_2 = 833.3 \text{ k}\Omega \quad r_{out} = r_{is} || R_S = 270.86 \text{ } \Omega \]
Alternate Solutions

Because the Thévenin resistance $R_{td}$ seen looking out of the drain is zero, the drain-source resistance $r_0$ connects from source to ground. In this case, an exact solution can be obtained with $r_0$ in the circuit. In cases where $R_{td} > 0$, let $r_0 = \infty$ (an open circuit) to obtain approximate solutions.

Source Equivalent Circuit Solution

(a) After making the Thévenin equivalent circuits looking out of the gate, replace the MOS-FET with the source equivalent circuit as shown in Fig. 6.

![Source equivalent circuit](image)

Figure 6: Source equivalent circuit.

(b) Solve for $v_o$.

$$v_o = v_{tg} \frac{r_0 || R_S || R_L}{r_s + r_0 || R_S || R_L} = v_i \frac{R_1 || R_2}{r_s + R_1 || R_2} \frac{r_0 || R_S || R_L}{r_s + r_0 || R_S || R_L}$$

(c) Solve for the voltage gain.

$$A_v = \frac{v_o}{v_i} = \frac{R_1 || R_2}{r_s + R_1 || R_2} \frac{r_0 || R_S || R_L}{r_s + r_0 || R_S || R_L}$$

(d) Solve for $r_{in}$.

$$r_{in} = R_1 || R_2$$

(e) Solve for $r_{out}$.

$$r_{out} = r_0 || r_s || R_S$$

Example 2 Use the source equivalent circuit solutions to calculate the values of $A_v$, $r_{in}$, and $r_{out}$ for Example 1.

$$A_v = 0.994 \times 0.893 = 0.888$$

$$r_{in} = R_1 || R_2 = 833.3 \text{ k}\Omega$$

$$r_{out} = 270.86 \text{ \Omega}$$
\( \pi \) Model Solution

(a) After making the Thévenin equivalent circuits looking out of the gate and source, replace the MOSFET with the \( \pi \) model as shown in Fig. 7.

(b) Solve for \( i_s' \).

\[
\begin{align*}
v_{tg} &= v_\pi + i_s' r_0 || R_S || R_L = \frac{i_d'}{g_m} + i_s' r_0 || R_S || R_L = \frac{i_d'}{g_m} + i_s' r_0 || R_S || R_L \\
\implies i_s' &= \frac{v_{tg}}{1 + g_0 || R_S || R_L}
\end{align*}
\]

(c) Solve for \( v_o \).

\[
\begin{align*}
v_o &= i_s' r_0 || R_S || R_L = \frac{v_{tg}}{1 + g_0 || R_S || R_L} r_0 || R_S || R_L \\
&= v_i \frac{R_1 || R_2}{R_s + R_1 || R_2} \frac{r_0 || R_S || R_L}{1 + g_0 || R_S || R_L}
\end{align*}
\]

(d) Solve for the voltage gain.

\[
A_v = \frac{v_o}{v_i} = \frac{R_1 || R_2}{R_s + R_1 || R_2} \frac{r_0 || R_S || R_L}{1 + g_0 || R_S || R_L}
\]

(e) Solve for \( r_{in} \).

\[
r_{in} = R_1 || R_2
\]

(f) Solve for \( r_{out} \). First, solve for the open-circuit output voltage. This is the output voltage with \( R_L = \infty \).

\[
v_{o(oc)} = v_{tg} \frac{r_0 || R_S}{1 + g_0 || R_S}
\]
Next, solve for the short-circuit output current. This is the output current with \( R_L = 0 \).
The output current is given by

\[
i_o = \frac{v_o}{R_L} = \frac{1}{g_m + r_0 \| R_s \| R_L} \frac{r_0 \| R_s \| R_L}{R_L} = \frac{v_{tg}}{g_m + r_0 \| R_s \| R_L} \frac{r_0 \| R_s \| R_L}{R_L + r_0 \| R_s \| R_L}
\]

Now, let \( R_L = 0 \) to obtain

\[
i_{o(sc)} = \frac{v_{tg}}{g_m} = g_m v_{tg}
\]

The output resistance is given by

\[
r_{out} = \frac{v_{o(oc)}}{i_{o(sc)}} = \frac{r_0 \| R_s \| R_L}{g_m + r_0 \| R_s \| R_L} = \frac{1}{g_m} \frac{r_0 \| R_s \| R_L}{R_L + r_0 \| R_s \| R_L}
\]

Note this is simply \( r_s \| r_0 \| R_s \), an answer that is obvious using the source equivalent circuit.

**Example 3** Use the \( \pi \) model solutions to calculate the values of \( A_v \), \( r_{in} \), and \( r_{out} \) for Example 1.

\[
A_v = 0.994 \times 0.893 = 0.888
\]

\[
r_{in} = R_1 \| R_2 = 833.3 \, k\Omega \quad r_{out} = 270.86 \, \Omega
\]

**T Model Solution**

(a) After making the Thévenin equivalent circuits looking out of the gate and source, replace the MOSFET with the T model as shown in Fig. 8.

(b) Solve for \( i'_s \).

\[
v_{tg} = i'_s \left( r_s + r_0 \| R_s \| R_L \right) \quad \Rightarrow \quad i'_s = \frac{v_{tg}}{r_s + r_0 \| R_s \| R_L}
\]
(c) Solve for $v_o$.

$$v_o = i'_s r_0 || R_S || R_L = \frac{v_{tg}}{r_s + r_0 || R_S || R_L} R_0 || R_S || R_L$$

$$= v_i \frac{R_1 || R_2}{r_s + R_1 || R_2} \frac{r_0 || R_S || R_L}{r_s + r_0 || R_S || R_L}$$

(d) Solve for the voltage gain.

$$A_v = \frac{v_o}{v_i} = \frac{R_1 || R_2}{r_s + R_1 || R_2} \frac{r_0 || R_S || R_L}{r_s + r_0 || R_S || R_L}$$

(e) Solve for $r_{in}$.

$$r_{in} = R_1 || R_2$$

(f) Solve for $r_{out}$. First, solve for the open-circuit output voltage. This is the output voltage with $R_L = \infty$.

$$v_o(oc) = v_{tg} \frac{r_0 || R_S}{r_s + r_0 || R_S}$$

Next, solve for the short-circuit output current. This is the output current with $R_L = 0$. The output current is given by

$$i_o = \frac{v_o}{R_L} = \frac{v_{tg}}{r_s + r_0 || R_S || R_L} \frac{r_0 || R_S || R_L}{R_L} = \frac{v_{tg}}{r_s + r_0 || R_S || R_L} \frac{r_0 || R_S}{R_L + r_0 || R_S}$$

Now, let $R_L = 0$ to obtain

$$i_o(sc) = \frac{v_{tg}}{r_s}$$

The output resistance is given by

$$r_{out} = \frac{v_o}{i_o(sc)} = \frac{r_0 || R_S}{r_s + r_0 || R_S} r_s = r_s || r_0 || R_S$$

This is the same answer obtained from the source equivalent circuit.

**Example 4** Use the T-model solutions to calculate the values of $A_v$, $r_{in}$, and $r_{out}$ for Example 1.

$$A_v = 0.994 \times 0.893 = 0.888$$

$$r_{in} = R_1 || R_2 = 833.3 \text{ k}\Omega$$

$$r_{out} = 270.86 \Omega$$
